Problem: Given n strings stored in memory, m query string.

For each query string s, determine whether there exists a string t in memory such that $|t| = |s|$, t differs in exactly one position.

Approach.

1. Store all given strings in a HashSet.
2. For each query string:
   - Try changing each character to every other possible character.
   - Check if modified string exists in the set.
3. If any modified string exists → answer is "yes"

* This ensures exactly one character change & same length.

Pesudo code.

```
# Input n, m

Create empty hash-set H.

For i = 1 to n:
    read string x.
    - found insert x into H.

For each query string:
    read string s.
    found = false.

    try changing each character, and if
    found in hashset answer is "Yes".
```

Pseudo Code:-

Input:

2 3
a aa a a
a ca caca
aabaa
ccacacc
caaac.

Output:

→ Yes
→ No
→ No.
